

Trapping Rainwater

height = [4, 2, 0, 6, 3, 2, 5]

→ Given n non-negative integers representing an elevation ^{height} map where the width of each bar is 1, compute how much water it can trap after raining.

We can assume these bar as a building.

यही trap water हमें compute करके जाना है।

small logical talk

→ by using formula
 $(w - x) * \text{width}$

1) $(4 - 4) * 1 = 0$

2) $(4 - 2) * 1 = 2$

3) $(4 - 0) * 1 = 4$

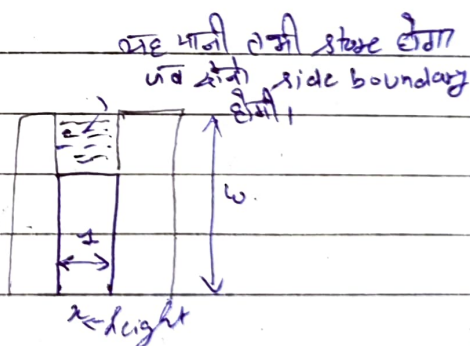

4) $(5 - 6) * 1 = -1$ means 0

5) $(5 - 3) * 1 = 2$

6) $(5 - 2) * 1 = 3$

7) $(5 - 5) * 1 = 0$

total 11

water trap = $(w - x) * \text{width}$

this is for खुद से कर रहे हैं। but यही चीज हमें तो है then हर बार तो हम water level predict नहीं कर पाएंगे so we need a logical formula.

1. Cases/ Scenario

1. if we have single bar

water trapped = 0 (beg water trap & final boundary
nahi hogi hai)

2. two bar

water trap = 0
(i) left side spill kar nikal
(ii) " " right " " "
(iii) both side spill kar nikal.

It means we need minimum 3 bar

$$\times \boxed{\text{min no. of bar} > 2}$$

3. Ascending / Descending \Rightarrow no water is trapped.

water trap = 0

4. Water trap & final we need boundary.

2nd or 3rd store height = 4 nahi hai isliye overflow kar nikal.

3rd mean right ki max boundary & left ki max boundary
& minimum boundary ka water store kar nahi hai

$$(4-2) \times \text{width} \\ (1-2 \times 1) = 2$$

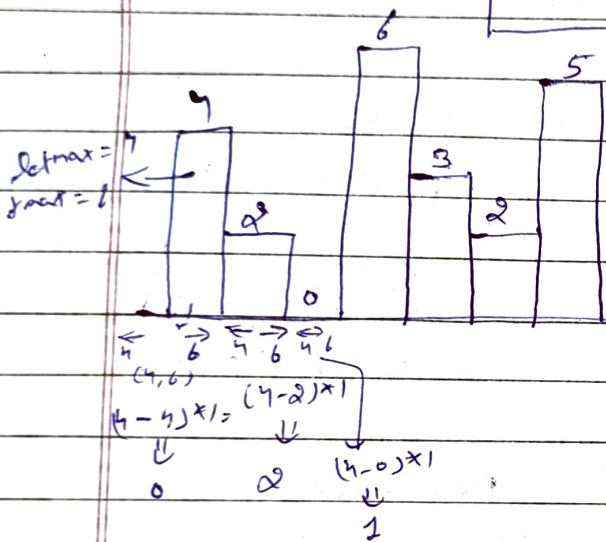

5

$$WL = \text{minimum}(\text{leftmaxboundary}, \text{rightmaxboundary})$$

$$\text{Trapped water} = (\text{Water level} - \text{height}) * \text{width}$$

$$\text{Water level} = \min(\text{max left boundary}, \text{max right boundary})$$

Left Max boundary

Right max boundary

→ Now question is how we calculate max boundary?

* for that we use auxillary arrays (helper arrays)

its like normal array but acts as helper.

so for calculating this we use left & right max boundary, which are calculated as follows.

Compare array ke left side ke bar ki max boundary ki bar ki height se compare krte. for e.g. bar 0 ke left, 2 bar ki highest/max krte, 2 ki max 4 hai but 0 ki right compare krte. 4 ko select kr lete.

It's not important ki ye question trapped water se hai aur, for e.g. maximum element se. pattern jump kr sakte hai.

Buy & Sell Stocks

You are given an array prices where prices[i] is the price of the price of a given stock on the ith day. You want to maximize your profit by choosing a single day to buy one stock and choosing a different day in the future to sell that stock. Return the maximum profit you can achieve from this transaction. If you cannot achieve any profit return 0.
(selling price) prices = [7, 1, 5, 3, 6, 4]

We know,

$$\text{profit} = \text{Selling price} - \text{Buying Price}$$

अगर हमें अधिकतम profit चाहिए तो हमें buy करना है & mark sell so that maximum profit मिले

Day 1

BP = 7

no loss
no profit

अगर day 1
हम buy करेंगे
तो हमें loss होगा

Day 2

SP = 1

BP = 7

$$P = 1 - 7 = -6$$

(x)

Day 3

SP = 5

BP = 1

$$P = 5 - 1 = 4$$

Day 4

SP = 3

BP = 1

$$P = 3 - 1 = 2$$

Day 5

SP = 6

BP = 1

$$P = 6 - 1 = 5$$

Day 6

SP = 4

BP = 1

$$P = 4 - 1 = 3$$

Buy Price =

back min price.

BP → buying price अतः हमें minimum price चाहिए

Var buy price = + ∞

→ back lowest buy price

Var max profit = 0

for (int i = 0 to n - 1)

(buy price < sell price) {

$$p = SP - BP$$

→ max profit ?

Case 1.

if buy price > sell price {

BP = sell price } Case 2
